Question 2:

2.1

```
# Prepare data for regression
reg_data <- iri %>%
  group_by(market_id) %>%
```

```
mutate(
  market_fe = as.factor(state),
  manufacturer_fe = as.factor(parent),
  time_fe = as.factor(week_id),
  brand_fe = as.factor(brand),
  p_jmt = price,
  total_sales = sum(quantity, na.rm = TRUE),
  sj = quantity / M,
  s0 = 1 - (total_sales / M),
  u = log(sj) - log(s0)
) %>%
ungroup()
```

Our estimation model is thus:

$$u_{jmt} = \alpha p_{jmt} + \beta \mathbb{X}_{jmt} + \xi_{jmt}$$

where $\mathbb{X}_{jmt}$ includes the product characteristics fiber, sugars, flavored, and fortified, as well as fixed effects for market, manufacturer, and time. and u_{jmt} is the log-odds of product j's market share in market m at time t.

2.2

```
# Regression model
reg_model <- lm(u ~ p_jmt + fiber + sugars + flavored + fortified +
               market_fe + manufacturer_fe + time_fe + brand_fe,
               data = reg_data)
summary(reg_model)
```

Call:

```
lm(formula = u ~ p_jmt + fiber + sugars + flavored + fortified +
    market_fe + manufacturer_fe + time_fe + brand_fe, data = reg_data)
```

Residuals:
